Problem 1.a.

(i) As an orthonormal set of basis functions we consider the set

$$\begin{aligned} \psi_1(t) &= \begin{cases} 1 & 0 \leq t < 1 \\ 0 & \text{o.w} \end{cases} & \psi_2(t) &= \begin{cases} 1 & 1 \leq t < 2 \\ 0 & \text{o.w} \end{cases} \\ \psi_3(t) &= \begin{cases} 1 & 2 \leq t < 3 \\ 0 & \text{o.w} \end{cases} & \psi_4(t) &= \begin{cases} 1 & 3 \leq t < 4 \\ 0 & \text{o.w} \end{cases} \end{aligned}$$

In matrix notation, the four waveforms can be represented as

$$\begin{pmatrix} s_1(t) \\ s_2(t) \\ s_3(t) \\ s_4(t) \end{pmatrix} = \begin{pmatrix} 2 & -1 & -1 & -1 \\ -2 & 1 & 1 & 0 \\ 1 & -1 & 1 & -1 \\ 1 & -2 & -2 & 2 \end{pmatrix} \begin{pmatrix} \psi_1(t) \\ \psi_2(t) \\ \psi_3(t) \\ \psi_4(t) \end{pmatrix}$$

Note that the rank of the transformation matrix is 4 and therefore, the dimensionality of the waveforms is 4

(ii) The representation vectors are

$$\begin{aligned} \mathbf{s}_1 &= [2 \ -1 \ -1 \ -1] \\ \mathbf{s}_2 &= [-2 \ 1 \ 1 \ 0] \\ \mathbf{s}_3 &= [1 \ -1 \ 1 \ -1] \\ \mathbf{s}_4 &= [1 \ -2 \ -2 \ 2] \end{aligned}$$

(iii) The distance between the first and the second vector is

$$d_{1,2} = \sqrt{|\mathbf{s}_1 - \mathbf{s}_2|^2} = \sqrt{[4 \ -2 \ -2 \ -1]^2} = \sqrt{25}$$

Similarly we find that

$$\begin{aligned} d_{1,3} &= \sqrt{|\mathbf{s}_1 - \mathbf{s}_3|^2} = \sqrt{[1 \ 0 \ -2 \ 0]^2} = \sqrt{5} \\ d_{1,4} &= \sqrt{|\mathbf{s}_1 - \mathbf{s}_4|^2} = \sqrt{[1 \ 1 \ 1 \ -3]^2} = \sqrt{12} \\ d_{2,3} &= \sqrt{|\mathbf{s}_2 - \mathbf{s}_3|^2} = \sqrt{[-3 \ 2 \ 0 \ 1]^2} = \sqrt{14} \\ d_{2,4} &= \sqrt{|\mathbf{s}_2 - \mathbf{s}_4|^2} = \sqrt{[-3 \ 3 \ 3 \ -2]^2} = \sqrt{31} \\ d_{3,4} &= \sqrt{|\mathbf{s}_3 - \mathbf{s}_4|^2} = \sqrt{[0 \ 1 \ 3 \ -3]^2} = \sqrt{19} \end{aligned}$$

Thus, the minimum distance between any pair of vectors is $d_{\min} = \sqrt{5}$.

Problem 1.b

i) The signal constellation is shown in the figure below.

From the signal constellation, we get $d_{min} = 2$. Since we have 5 signals, the Union Bound is given by,

$$\begin{aligned} P_e &\leq 4 Q\left(\frac{d_{min}}{2\sigma}\right) \\ &= 4 Q\left(\frac{1}{\sigma}\right). \end{aligned}$$

ii) The number of Nearest Neighborhood $N_e = 1/5(2+2+3+3+2) = 2.4$. Therefore, the Nearest Neighborhood Union Bound is given by,

$$P_e = 2.4 Q\left(\frac{1}{\sigma}\right).$$

iii) Since $\mathcal{E}_x = \frac{1}{5}(2 \times 4 + 3^2) = 3.4$,

$$\sigma = \sqrt{\frac{\mathcal{E}_x}{SNR}} = \sqrt{\frac{\frac{1}{2}\mathcal{E}_x}{SNR}} = \sqrt{\frac{1.7}{10^{1.4}}}$$

Therefore, we get

$$P_e(\text{NNUB}) = 2.4 \times Q\left(\sqrt{\frac{10^{1.4}}{1.7}}\right) = 1.45 \times 10^{-4}.$$

Problem 1.c

i)

The impulse response of the matched filter is

$$s(t) = u(T-t) = \begin{cases} \frac{A}{T}(T-t) \cos(2\pi f_c(T-t)) & 0 \leq t \leq T \\ 0 & \text{otherwise} \end{cases}$$

ii)

The output of the matched filter at $t = T$ is

$$\begin{aligned} g(T) &= u(t) * s(t)|_{t=T} = \int_0^T u(T-\tau) s(\tau) d\tau \\ &= \frac{A^2}{T^2} \int_0^T (T-\tau)^2 \cos^2(2\pi f_c(T-\tau)) d\tau \\ &\stackrel{v=T-\tau}{=} \frac{A^2}{T^2} \int_0^T v^2 \cos^2(2\pi f_c v) dv \\ &= \frac{A^2}{T^2} \left[\frac{v^3}{6} + \left(\frac{v^2}{4 \times 2\pi f_c} - \frac{1}{8 \times (2\pi f_c)^3} \right) \sin(4\pi f_c v) + \frac{v \cos(4\pi f_c v)}{4(2\pi f_c)^2} \right] \Bigg|_0^T \\ &= \frac{A^2}{T^2} \left[\frac{T^3}{6} + \left(\frac{T^2}{4 \times 2\pi f_c} - \frac{1}{8 \times (2\pi f_c)^3} \right) \sin(4\pi f_c T) + \frac{T \cos(4\pi f_c T)}{4(2\pi f_c)^2} \right] \end{aligned}$$

Problem 1.d

The maximum likelihood criterion selects the maximum of $f(\mathbf{r}|s_m)$ over the M possible transmitted signals. When $M = 2$, the ML criterion takes the form

$$\frac{f(\mathbf{r}|s_1)}{f(\mathbf{r}|s_2)} \underset{s_2}{\overset{s_1}{>}} 1$$

or, since

$$\begin{aligned} f(\mathbf{r}|s_1) &= \frac{1}{\sqrt{\pi N_0}} e^{-(r-\sqrt{\mathcal{E}_b})^2/N_0} \\ f(\mathbf{r}|s_2) &= \frac{1}{\sqrt{\pi N_0}} e^{-(r+\sqrt{\mathcal{E}_b})^2/N_0} \end{aligned}$$

the optimum maximum-likelihood decision rule is

$$\underset{s_2}{\overset{s_1}{r >}} 0$$

The average probability of error is given by

$$\begin{aligned} P(e) &= p \int_0^\infty \frac{1}{\sqrt{\pi N_0}} e^{-(r+\sqrt{\mathcal{E}_b})^2/N_0} dr + (1-p) \int_{-\infty}^0 \frac{1}{\sqrt{\pi N_0}} e^{-(r-\sqrt{\mathcal{E}_b})^2/N_0} dr \\ &= p \int_{\sqrt{2\mathcal{E}_b/N_0}}^\infty \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx + (1-p) \int_{-\infty}^{-\sqrt{2\mathcal{E}_b/N_0}} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx \\ &= pQ \left[\sqrt{\frac{2\mathcal{E}_b}{N_0}} \right] + (1-p)Q \left[\sqrt{\frac{2\mathcal{E}_b}{N_0}} \right] \\ &= Q \left[\sqrt{\frac{2\mathcal{E}_b}{N_0}} \right] \end{aligned}$$

Problem 2.a

i

The energy of the 64 QAM is given by,

$$\mathcal{E}_x(64) = \frac{d^2}{6}(M - 1) = 42$$

The energy of the hybrid 32 QAM constellation is found as follows. The 64 QAM can be decomposed into two 32 hybrid QAM constellations: The first one represented by dots, and the other one represented by \times . Since these two constellations are rotations of one another, then their energies must be equal. The energy of the 64 QAM constellation is then,

$$\mathcal{E}_x(64) = \frac{1}{2}\mathcal{E}_x(32) + \frac{1}{2}\mathcal{E}_x(32)$$

(The factor of 1/2 is present because we have 32 points in each hybrid constellation, and 64 points in the square QAM constellation). Therefore, $\mathcal{E}_x(32) = 42$. The energies are the same.

ii

The NNUB probability of error for the 64 QAM constellation is,

$$P_e \leq 4\left(1 - \frac{1}{\sqrt{M}}\right)Q\left(\frac{d}{2\sigma}\right)$$

$$\Leftrightarrow P_e \leq 3.5Q\left(\frac{1}{\sigma}\right)$$

To find the NNUB for the 32 hybrid QAM the number of nearest neighbors N_e has to be computed. The constellation points are divided as follows,

- Inner Points (26) have 4 neighbors.
- Side Points (6) have 3 neighbors.

Therefore, $N_e = \frac{1}{32}[26 \times 4 + 6 \times 3] = 3\frac{13}{16}$. Since $d_{min} = 2\sqrt{2}$, then,

$$P_e \leq 3.8125Q\left(\frac{\sqrt{2}}{\sigma}\right)$$

iii

The distance d^2 is given by,

$$d^2 = \frac{6\mathcal{E}_x}{\frac{31}{32}M - 1} = 8.4$$

$$\Leftrightarrow d = \sqrt{8.4} \simeq 2.898$$

iv

The probability of error for the 32 Cross QAM is,

$$P_e \leq 3.5Q\left(\frac{\sqrt{2.1}}{\sigma}\right)$$

For the 32 hybrid QAM constellation, $P_e \leq 3.8125Q\left(\frac{\sqrt{2}}{\sigma}\right)$. Since the argument of the Q function for the 32 Cross QAM is bigger than the one for the 32 hybrid constellation - equivalently $d(cross) > d(hybrid)$, 32 Cross performs better.

v

The constellation figure of merit for both constellations is,

$$CFM(hybrid) = \frac{d^2/4}{\mathcal{E}_x} = \frac{2}{21} = 0.0952,$$

$$CFM(cross) = \frac{\frac{8.4}{4}}{21} = 0.1$$

Obviously, $CFM(cross) > CFM(hybrid)$, a result that is consistent with (d).

Problem 2.b

The three symbols A , 0 and $-A$ are used with equal probability. Hence, the optimal detector uses two thresholds, which are $\frac{A}{2}$ and $-\frac{A}{2}$, and it bases its decisions on the criterion

$$\begin{aligned} A: & \quad r > \frac{A}{2} \\ 0: & \quad -\frac{A}{2} < r < \frac{A}{2} \\ -A: & \quad r < -\frac{A}{2} \end{aligned}$$

If the variance of the AWG noise is σ_n^2 , then the average probability of error is

$$\begin{aligned} P(e) &= \frac{1}{3} \int_{-\infty}^{\frac{A}{2}} \frac{1}{\sqrt{2\pi\sigma_n^2}} e^{-\frac{(r-A)^2}{2\sigma_n^2}} dr + \frac{1}{3} \left(1 - \int_{-\frac{A}{2}}^{\frac{A}{2}} \frac{1}{\sqrt{2\pi\sigma_n^2}} e^{-\frac{r^2}{2\sigma_n^2}} dr \right) \\ &\quad + \frac{1}{3} \int_{-\frac{A}{2}}^{\infty} \frac{1}{\sqrt{2\pi\sigma_n^2}} e^{-\frac{(r+A)^2}{2\sigma_n^2}} dr \\ &= \frac{1}{3} Q \left[\frac{A}{2\sigma_n} \right] + \frac{1}{3} 2Q \left[\frac{A}{2\sigma_n} \right] + \frac{1}{3} Q \left[\frac{A}{2\sigma_n} \right] \\ &= \frac{4}{3} Q \left[\frac{A}{2\sigma_n} \right] \end{aligned}$$

Problem 2.c

(i)

Since QAM transmission is used,

$$\begin{aligned}\phi_1 &= -\sqrt{\frac{2}{T}} \operatorname{sinc}\left(\frac{t}{T}\right) \sin \omega_c t \\ \phi_2 &= \sqrt{\frac{2}{T}} \operatorname{sinc}\left(\frac{t}{T}\right) \cos \omega_c t\end{aligned}$$

(ii) where $T = 2 \cdot 10^{-7}$.

For QAM and $P_e = 10^{-6}$ the gap is $\Gamma = 8.8 \text{ dB}$. Hence,

$$\bar{b} = \frac{1}{2} \log_2 \left(1 + \frac{SNR}{\Gamma} \right) \simeq 3$$

(iii)

Then, $R = \frac{\bar{b}}{T} = \frac{2.3}{2 \cdot 10^{-7}} = 30 \text{ Mbps}$.

Since $\bar{b} = 3, b = 6$, we have $M = 2^b = 2^6 = 64$. Therefore this is a 64-square QAM signal constellation.

(iv)

In order to achieve $R = 35 \text{ Mbps}$, we should have $b = 7$, thus employing 128-cross QAM. We require the same probability of error, so:

$$\begin{aligned}\left(\frac{d_{min}}{2\sigma} \right)^2 &= \frac{3SNR}{\frac{31}{32}M - 1} = 13.5 \text{ dB} \Rightarrow \\ SNR &= 917.9 = 29.6 \text{ dB}\end{aligned}$$

f

Problem 3.a

(i) We will proceed using the gap approximation: i.e. $E_n(b_n) = \frac{\Gamma}{g_n}(2^{2b_n} - 1) * k$, where $k=1$ if PAM and $k=2$ if QAM.

So, we first need to find $g_n = \frac{|H_n|^2}{\sigma_n^2}$. From the system parameters $\sigma_n^2 = .125$. So, we have the following table (the center 3 are QAM channels)

subchannel	0	1	2	3	4
g_n	18	15.6569	10	4.3431	2

Now, using the above formula, we get:

subchannel	0	1	2	3	4
$e_n(1)$	1.2463	.9690	1.5172	3.4932	11.37
$e_n(2)$	5.07	1.938	3.043	6.9860	45.5233
$e_n(3)$	19.2287	3.8760	6.0686	13.97	182.0567
$e_n(4)$	81.9150	7.7521	12.1372	27.94	728.2345

Note for the QAM channels we could have used $e_n(b_n) = \frac{\Gamma}{g_n} 2^{2b_n}$

With the above table, it is obvious that the bit allocations are as follows:

(ii)

subchannel	0	1	2	3	4
b_n	2	3	2	1	0
$E_n(b_n)$	6.3215	6.7830	4.5515	3.4932	0

Bits were chosen in the following order: 1,0,2,1,2,3,1,0

$N * \bar{E}_x = 8$, so we are way over budget. Working backwards, we get

(iii)

subchannel	0	1	2	3	4
b_n	1	2	1	0	0
$E_n(b_n)$	1.2463	2.9070	1.5172	0	0

(iv)

Again, we just work backwards

subchannel	0	1	2	3	4
b_n	1	1	0	0	0
$E_n(b_n)$	1.2463	.9690	0	0	0

The margin in this case is $10 * \log_{10}(\frac{8}{1.2463+.9690}) = 5.577dB$

(i)

Problem 3.b

g =

b_bar =

1.0622

3.c

i

From Problem 3.b, a rate of 1.06 is achieved with a gap of 4.23 dB. Since $\Gamma = 9.8\text{dB}$ for $P_e = 10^{-7}$, about 4.5 dB more energy is needed. So, the P_e goal cannot be achieved. We can reach the same conclusion by doing MA, which will give us a negative margin.

ii

Since we get $R = 1.0622$ for $\Gamma = 4.23\text{dB}$ from 3.b, an easy way to solve this one would be to try a slightly larger gap than 4.23dB. To get the exact gap value, we need to solve MA again. The same **approach** as in problem 3. will give us $\Gamma = 4.79\text{dB}$, and the corresponding $P_e = 1.3 \cdot 10^{-3}$.

iii

Part ii gives us $\Gamma = 4.79\text{dB}$ with no margin. So, with $\Gamma = 0$, margin = 4.79dB.

Problem 4.a

Substituting the expression of $X_{rc}(f)$ in the desired integral, we obtain

$$\begin{aligned}
 \int_{-\infty}^{\infty} X_{rc}(f) df &= \int_{-\frac{1+\alpha}{2T}}^{-\frac{1-\alpha}{2T}} \frac{T}{2} \left[1 + \cos \frac{\pi T}{\alpha} \left(-f - \frac{1-\alpha}{2T} \right) \right] df + \int_{-\frac{1-\alpha}{2T}}^{\frac{1-\alpha}{2T}} T df \\
 &\quad + \int_{\frac{1-\alpha}{2T}}^{\frac{1+\alpha}{2T}} \frac{T}{2} \left[1 + \cos \frac{\pi T}{\alpha} \left(f - \frac{1-\alpha}{2T} \right) \right] df \\
 &= \int_{-\frac{1+\alpha}{2T}}^{-\frac{1-\alpha}{2T}} \frac{T}{2} df + T \left(\frac{1-\alpha}{T} \right) + \int_{\frac{1-\alpha}{2T}}^{\frac{1+\alpha}{2T}} \frac{T}{2} df \\
 &\quad + \int_{-\frac{1+\alpha}{2T}}^{-\frac{1-\alpha}{2T}} \cos \frac{\pi T}{\alpha} \left(f + \frac{1-\alpha}{2T} \right) df + \int_{\frac{1-\alpha}{2T}}^{\frac{1+\alpha}{2T}} \cos \frac{\pi T}{\alpha} \left(f - \frac{1-\alpha}{2T} \right) df \\
 &= 1 + \int_{-\frac{\alpha}{T}}^0 \cos \frac{\pi T}{\alpha} x dx + \int_0^{\frac{\alpha}{T}} \cos \frac{\pi T}{\alpha} x dx \\
 &= 1 + \int_{-\frac{\alpha}{T}}^{\frac{\alpha}{T}} \cos \frac{\pi T}{\alpha} x dx = 1 + 0 = 1
 \end{aligned}$$

Problem 4.b

i

The pulse response is $p(t) = \phi(t) * h(t)$. In frequency domain,

$$\begin{aligned} P(f) &= \Phi(f)H(f) \\ &= (\sqrt{T} \Pi(Tf)) \left(\frac{1}{1 + ae^{j2\pi f}} \Pi(f) \right) \\ &= \frac{1}{1 + ae^{j2\pi f}} \Pi(f) \quad (\text{since } T=1) \end{aligned}$$

In terms of ω ,

$$P(\omega) = \begin{cases} \frac{1}{1+ae^{j\omega}} & |\omega| \leq \pi \\ 0 & |\omega| > \pi \end{cases}$$

ii

First, let's find $P(e^{-j\omega T})$.

$$P(e^{-j\omega T}) = \frac{1}{T} \sum_{n=-\infty}^{\infty} P(\omega + \frac{2\pi n}{T})$$

Since $T=1$ and $P(\omega) = 0$ for $|\omega| > \pi$, $P(e^{-j\omega T}) = \frac{1}{1+ae^{j\omega}}$. Then, by the inverse Fourier transform,

$$p_k = (-a)^{-k} u[-k].$$

Therefore,

$$\begin{aligned} \|p\|^2 &= T \sum_{k=-\infty}^{\infty} |p_k|^2 \\ &= \sum_{k=-\infty}^0 (-a)^{2k} \\ &= \sum_{k=0}^{\infty} (-a)^{2k} \\ &= \frac{1}{1-a^2}. \end{aligned}$$

iii

By substituting $e^{-j\omega T} = D$ into $P(e^{-j\omega T})$, we get $P(D) = \frac{1}{1+aD^{-1}}$.

Therefore,

$$Q(D) = \frac{T}{\|p\|^2} P(D) P^*(D^{-*}) = \frac{1-a^2}{(1+aD)(1+aD^{-1})}$$

(i)

For the zero-forcing equalizer,

$$W_{ZFE}(D) = \frac{1}{\|p\|Q(D)} = \frac{(1+aD)(1+aD^{-1})}{\sqrt{1-a^2}}.$$

To calculate $W_{MMSE-LE}(D)$, we need SNR_{MFB} :

$$SNR_{MFB} = \frac{\|p\|^2 \overline{\mathcal{E}_x}}{\sigma^2} = \frac{10^{1.5}}{1-a^2}.$$

Then,

$$\begin{aligned} W_{MMSE-LE}(D) &= \frac{1}{\|p\|(Q(D) + 1/SNR_{MFB})} \\ &= \frac{\sqrt{1-a^2}}{\frac{1-a^2}{(1+aD)(1+aD^{-1})} + \frac{1+a^2}{10^{1.5}}} \\ &= \frac{(1+aD)(1+aD^{-1})}{\sqrt{1-a^2}[1 + (1+aD)(1+aD^{-1})10^{-1.5}]} \end{aligned}$$

(ii)

When $a = 0$, $Q(D) = 1$ and $\|p\|^2 = 1$. Since $SNR = 15\text{dB}$ and $\Gamma = 8.8\text{dB}$ at $P_e = 10^{-6}$,

$$\bar{b} = \frac{1}{2} \log_2 \left(1 + \frac{10^{1.5}}{10^{0.88}} \right) = 1.18$$

Then, the maximum data rate achievable is

$$R = \frac{b}{T} = \frac{1.18}{1} = 1.18 \text{ bits/sec}$$

Problem 4.c

The bandwidth of the bandpass channel is $W = 4$ KHz. Hence, the rate of transmission should be less or equal to 4000 symbols/sec. If a 8-QAM constellation is employed, then the required symbol rate is $R = 9600/3 = 3200$. If a signal pulse with raised cosine spectrum is used for shaping, the maximum allowable roll-off factor is determined by

$$1600(1 + \alpha) = 2000$$

which yields $\alpha = 0.25$. Since α is less than 50%, we consider a larger constellation. With a 16-QAM constellation we obtain

$$R = \frac{9600}{4} = 2400$$

and

$$1200(1 + \alpha) = 2000$$

Or $\alpha = 2/3$, which satisfies the required conditions. The probability of error for an M -QAM constellation is given by

$$P_M = 1 - (1 - P_{\sqrt{M}})^2$$

where

$$P_{\sqrt{M}} = 2 \left(1 - \frac{1}{\sqrt{M}}\right) Q \left[\sqrt{\frac{3\mathcal{E}_{av}}{(M-1)N_0}} \right]$$

With $P_M = 10^{-6}$ we obtain $P_{\sqrt{M}} = 5 \times 10^{-7}$ and therefore

$$2 \times \left(1 - \frac{1}{4}\right) Q \left[\sqrt{\frac{3\mathcal{E}_{av}}{15 \times 2 \times 10^{-10}}} \right] = 5 \times 10^{-7}$$

Using the last equation and the tabulation of the $Q[\cdot]$ function, we find that the average transmitted energy is

$$\mathcal{E}_{av} = 24.70 \times 10^{-9}$$

Note that if the desired spectral characteristic $X_{rc}(f)$ is split evenly between the transmitting and receiving filter, then the energy of the transmitting pulse is

$$\int_{-\infty}^{\infty} g_T^2(t) dt = \int_{-\infty}^{\infty} |G_T(f)|^2 df = \int_{-\infty}^{\infty} X_{rc}(f) df = 1$$

Hence, the energy $\mathcal{E}_{av} = P_{av}T$ depends only on the amplitude of the transmitted points and the symbol interval T . Since $T = \frac{1}{2400}$, the average transmitted power is

$$P_{av} = \frac{\mathcal{E}_{av}}{T} = 24.70 \times 10^{-9} \times 2400 = 592.8 \times 10^{-7}$$

If the points of the 16-QAM constellation are evenly spaced with minimum distance between them equal to d , then there are four points with coordinates $(\pm \frac{d}{2}, \pm \frac{d}{2})$, four points with coordinates $(\pm \frac{3d}{2}, \pm \frac{3d}{2})$, four points with coordinates $(\pm \frac{5d}{2}, \pm \frac{5d}{2})$, and four points with coordinates $(\pm \frac{7d}{2}, \pm \frac{7d}{2})$. Thus, the average transmitted power is

$$P_{av} = \frac{1}{2 \times 16} \sum_{i=1}^{16} (A_{mc}^2 + A_{ms}^2) = \frac{1}{2} \left[4 \times \frac{d^2}{2} + 4 \times \frac{9d^2}{2} + 8 \times \frac{10d^2}{4} \right] = 20d^2$$

Since $P_{av} = 592.8 \times 10^{-7}$, we obtain

$$d = \sqrt{\frac{P_{av}}{20}} = 0.00172$$
